# Introduction

## Social capital as a growth theory

- Theories explaining economic growth: geography, demography, institutions, education, financial development and...**social capital**
- Durlauf and Fafchamfs (2005): “A set of informal forms of institutions and organizations based on social relationships, networks and associations that create shared knowledge, mutual trust, social norms and unwritten rules”
- Some **classical contributions** are Putnam (1993); Knack and Keefer (1997); Zak and Knack (2001).
- Some **recent contributions** include Akçomak and Ter Weel, 2009; Dearmon and Grier (2009, 2011), Peiró-Palomino and Tortosa-Ausina (2013, 2014) Bjørnskov, (2006, 2012), Bjørnskov et al. (2013), Westlund et al. (2009, 2011, 2013).

- Social capital stimulates economic growth throughout a variety of **channels**:
  - Helps in solving problems of collective action
  - Reduces monitoring costs
  - Facilitates complex agreements by mitigating information asymmetries
  - Eases knowledge diffusion and innovation processes
  - Other (indirect) effects: financial development (Guiso et al., 2004), human capital (Bjørnskov, 2009; Dearmon and Grier, 2011), investment (Zak and Knack, 2001; Dearmon and Grier, 2011; Peiró-Palomino and Tortosa-Ausina, 2013b) or trade (Guiso et al., 2009)
  - But...sometimes can be also **negative**

# Introduction

## Social capital and growth in the European context

- European regional setting: **mixed results** in a frame of growth regressions with the most common indicators: trust, associational life and civic norms
- Schneider et al. (2000): trust negatively related to growth
- Beugelsdijk and Van Schaik (2005): trust nonsignificant but associational activities positive and significantly related to growth (especially active participation)
- Akçomak and Ter Weel (2009): trust fosters innovation but not directly related to growth
- Peiró-Palomino, Forte and Tortosa-Ausina (2014): trust, associations and civic norms related to higher growth (using Bayesian methods)

# Introduction

## Social capital and growth in the European context

- Most studies are exclusively focused on Western Europe, while evidence for **Eastern and Central Europe (ECE)** is very scant (Peiró-Palomino, Forte and Tortosa-Ausina, 2014 analyzed a sample of 85 NUTS 1 including ECE regions)
- Considering ECE regions is important for some reasons:
  - Social capital in ECE regions is lower than in Western regions. Some authors (see Rose, 2000; Paldam and Svendsen, 2001; Zúkowski, 2007 and Fidrmuc and Gërkhani, 2008) suggest this is a consequence of the communist experience, which modified social patterns and negatively affected social capital
  - ECE regions have experienced higher growth in recent times and they are catching up their Western peers (see Crespo-Cuaresma, et al. 2012)

- Most studies are exclusively focused on Western Europe, while evidence for **Eastern and Central Europe (ECE)** is very scant (Peiró-Palomino, Forte and Tortosa-Ausina, 2014 analyzed a sample of 85 NUTS 1 including ECE regions)

# Introduction

## Objectives of the paper

- Analyzing the role of social capital in the enlarged EU (237 regions during the period 1995–2007)
- Two indicators: trust and associational life (active participation)
- Use of **nonparametric regression** which permits shed light on:
  - Potential nonlinearities of the parameters
  - Regional parameter heterogeneity

# Empirical methodology

## Parametric and nonparametric regressions

- Parametric (**OLS**) regressions

$$Y_i = \beta_0 + \sum_{j=1}^v \beta_j Z_{ji} + \epsilon_i, i = 1, 2, \dots, n, \quad (1)$$

- Nonparametric (**kernel**) regressions

$$Y_i = m(Z_i) + \epsilon_i, i = 1, 2, \dots, n, \quad (2)$$

- $m(\cdot)$  is an **unknown smooth function** capturing the conditional relationship between the dependent and the independent variables in the model
- Some alternatives to compute  $m(Z_i)$  based on the methods proposed by Li and Racine (2004) and Racine and Li (2004)
- Generalized product kernel methods, valid for both continuous and categorical variables
- Nonparametric regression permits estimating individual effects for every sample point (parameter heterogeneity)
- Neither a predefined functional form nor a distribution of the error term is required

# Empirical methodology

## Parametric and nonparametric regressions

- Parametric (**OLS**) regressions

$$Y_i = \beta_0 + \sum_{j=1}^v \beta_j Z_{ji} + \epsilon_i, i = 1, 2, \dots, n, \quad (1)$$

- Generalized product kernel methods, valid for both continuous and categorical variables
- Nonparametric regression permits estimating individual effects for every sample point (parameter heterogeneity)
- Neither a predefined functional form nor a distribution of the error term is required

- **Local-Constant Least Squares (LCLS)**
- Particularly useful to identify **relevancy** of the regressors
- Estimates  $m(\cdot)$  by calculating a local weighted average of the dependent variable  $Y_i$  considering the observations with similar values of the independent variables  $Z_i$
- The **bandwidths** determine the quantity of averaged observations around each point  $z_i$
- The estimator obeys to the following expression

$$\hat{m}(z) = \frac{\sum_{i=1}^n y_i \prod_{s=1}^q K\left(\frac{z_{sj} - z_s}{h_s}\right)}{\sum_{i=1}^n \prod_{s=1}^q K\left(\frac{z_{sj} - z_s}{h_s}\right)} \quad (3)$$

# Empirical methodology

# Empirical methodology

## Nonparametric regression, estimation alternatives

- Local-Linear Least Squares (LLLS)
- Suitable to detect **nonlinearities** of the regressors
- It computes a weighted least-squares regression around every point  $z_i$ .
- Weights established by a kernel function and a bandwidth vector such that those observations closer to  $z_i$  receive more weight
- The estimator obeys to the following expression

$$Y_i \approx m(z) + (z_i^c - z^c)\beta(z^c) + \epsilon_i \quad (4)$$

$$\hat{\delta}(z) = [Z'K(z)Z]^{-1}Z'K(z)y \quad (5)$$

- Following Li and Racine (2007), a second-order Gaussian kernel is selected for continuous variables whereas for categorical variables the choice is the Aitchison and Aitken (1976) kernel

# Empirical methodology

## Nonparametric regression, estimation alternatives

- Local-Linear Least Squares (LLLS)

## Nonparametric regression, estimation alternatives

- Local-Linear Least Squares (LLLS)
- Suitable to detect **nonlinearities** of the regressors
- It computes a weighted least-squares regression around every point  $z_i$ .
- Weights established by a kernel function and a bandwidth vector such that those observations closer to  $z_i$  receive more weight
- The estimator obeys to the following expression

$$Y_i \approx m(z) + (z_i^c - z^c)\beta(z^c) + \epsilon_i \quad (4)$$

$$\hat{\delta}(z) = [Z'K(z)Z]^{-1}Z'K(z)y \quad (5)$$

- Following Li and Racine (2007), a second-order Gaussian kernel is selected for continuous variables whereas for categorical variables the choice is the Aitchison and Aitken (1976) kernel

# Empirical methodology

## Nonparametric regression, estimation alternatives

- Local-Linear Least Squares (LLLS)
- Suitable to detect **nonlinearities** of the regressors
- It computes a weighted least-squares regression around every point  $z_i$ .
- Weights established by a kernel function and a bandwidth vector such that those observations closer to  $z_i$  receive more weight
- The estimator obeys to the following expression

$$Y_i \approx m(z) + (z_i^c - z^c)\beta(z^c) + \epsilon_i \quad (4)$$

$$\hat{\delta}(z) = [Z'K(z)Z]^{-1}Z'K(z)y \quad (5)$$

- Following Li and Racine (2007), a second-order Gaussian kernel is selected for continuous variables whereas for categorical variables the choice is the Aitchison and Aitken (1976) kernel

# Empirical methodology

## Nonparametric regression, estimation alternatives

- Independently of the approach, the important choice is not the kernel, but the bandwidth (in general in all nonparametric procedures)
- Unappropriate bandwidths may produce estimates with low variance and high bias (**undersmoothing**), or high variance and low bias (**oversmoothing**)
- Bandwidths are selected using **least-squares cross-validation (LSCV)**, an automated bandwidth selection procedure
- The bandwidths not only determine the degree of smoothing:
  - In LCLS when the bandwidth associated to one regressor hits its upper bound (UB), it denotes **irrelevancy**
  - In LLLS when the bandwidth associated to one regressor hits its upper bound (UB), it denotes **linearity**
  - UB are defined as two standard deviations for continuous variables and  $(q_s - 1)/q_s$  for categorical variables (with  $q_s$  the number of values the variable can take)

# Empirical methodology

## Nonparametric regression, estimation alternatives

# Models, sample and data sources

- **Sample of 237 European regions (NUTS 2)**
- Period of analysis 1995–2007. Two subperiods (1995–2002) and (2003–2007)
- Neoclassical growth equation (Solow, 1957) augmented with social capital
- TRUST: percentage of respondents who declared trusting others in the social trust question. Source: EVS (1999)
- ACTIVE: percentage of people who voluntarily participate in at least one association (from 15 different). Source: EVS (1999)
- Controls: initial GDP ( $GDP_0$ ), population growth (GPOP), capital formation (GFCF), human capital (HC), and capital city (CAPITAL). Source: Eurostat (1995–2007)
- Different models (1–5) where the variables are included sequentially
- Data constraints on the social capital variables. (NUTS 1 level aggregation)

# Results, nonparametric regressions

## Dealing with endogeneity

- **Endogeneity** issues should not be a problem in the context of social capital due to the stability of social values over time
- Unfortunately, most of the referees in academic journals do not agree on this
- In the nonparametric framework, technical alternatives to deal with this problem are very recent and empirical applications of these methods virtually nonexistent (see, Henderson et al, 2013)
- Here the Su and Ullah (2008) procedure is used. It consists of the following two steps:
  - Stage I: LCLS estimation on the endogenous variables over a set of suitable instruments
  - Stage II: LLLS estimation on the original regression, including both the endogenous and the exogenous variables as well as the adjusted residuals from Stage I.
  - Selection of instruments: Nobel strategy by Henderson's et al, (2013): The control variables instrument social capital

# Outline

- 1 Introduction
- 2 Empirical methodology
- 3 Model, sample and descriptive statistics
- 4 Results, parametric regressions
- 5 Results, nonparametric regressions
- 6 Conclusions**

# Conclusions

- The linear specification imposed by the parametric methods is not the true underlying relationship between the two indicators of social capital and growth
- TRUST is not significant in the parametric analysis (in line with previous research for the European regions), but it is significant in the nonparametric one
- ACTIVE is significant in both the parametric and the nonparametric estimation
- The average coefficient provided by the parametric analysis simply does not reflect the effect of social capital in some regions
- The greatest differences appear when comparing ECE and non ECE regions.
- Some policy suggestions:
  - The existent stock of social capital in each region should be considered
  - Policies should be applied carefully in some regions where they might yield undesired effects

# Conclusions
