Per capita GDP since the end of the Reconquista (logs)

How Has a Growing Per Capita GDP Been Distributed over Time?

- Did growth reach the bottom of the *income distribution*?
- Was there a *growth-inequality trade-off*?
- But lack of *pre-1970s micro evidence (HHS)*

The Simplest Case of Income Distribution: Property Owners and Workers Only

The evolution of income **inequality** *depends on*

- the **gap** *between* the groups' average incomes
- the **dispersion** of incomes *within* each group

Stylized facts

- in **early** stages of development, inequality is **driven** by the **gap** *between* average returns of proprietors and workers
- as progress takes place, the *dispersion* of factor returns (**labour**, in particular) leads *personal* income distribution

How to infer long-run trends in inequality? (1)

A) land rent / unskilled wage ratio

Caveat

- Only *representative* in **pre-industrial** societies in which *land* and *unskilled labour* are the **main production factors**

How to infer long-run trends in inequality? (2)

B) Williamson *inequality index*

- *GDP per worked hour / Unskilled wage* (***y/wus***)

- *rationale:*

numerator captures *returns* to **all** factors of production;
denominator, only *returns* to **raw labour**

Caveat

- As societies progress, ***y/wus*** exaggerates inequality
=> the *share* of *unskilled workers* in labour **dwindles**
- *Time comparisons* become **inconsistent**:
the *quantile* of income of *unskilled workers* today,
a **fraction** of the same *quantile* in the **past**

Two Regimes in Pre-industrial Spain

- 1270-1570

- a **high** land-labour ratio **frontier** economy, largely **pastoral**, **trade-oriented**, led by **towns**
=> **high wages & food consumption, low inequality**

- 1600-1820

- a more **agricultural** and **densely** populated, **low wage**, **unequal** economy
=> **growth** along a **lower path**

Reconciling Partial Measures of Inequality

The *Gini* can be expressed as,

$$Gini = \sum_{[A]} G_i p_i \pi_i + \sum_{[B]} ((y_p - y_l) / y_l) \pi_l p_p + L \quad [L]$$

- $\sum G_i p_i \pi_i$ (**Gini A**),
weighted sum of **within-group inequality**
- $\sum ((y_p - y_l) / y_l) \pi_l p_p$ (**Gini B**),
between-group inequality
- (**L**) is the **overlapping component**, or residual
